A **computer** is a <u>digital electronic machine</u> that can be programmed to <u>carry out sequences</u> of <u>arithmetic</u> or <u>logical operations</u> (<u>computation</u>) automatically. Modern computers can perform generic sets of operations known as <u>programs</u>. These programs enable computers to perform a wide range of tasks. A **computer system** is a "complete" computer that includes the <u>hardware</u>, <u>operating system</u> (main <u>software</u>), and <u>peripheral</u> equipment needed and used for "full" operation. This term may also refer to a group of computers that are linked and function together, such as a <u>computer network</u> or <u>computer cluster</u>.

A broad range of <u>industrial</u> and <u>consumer products</u> use computers as <u>control</u> <u>systems</u>. Simple special-purpose devices like <u>microwave ovens</u> and <u>remote</u> <u>controls</u> are included, as are factory devices like <u>industrial robots</u> and <u>computer-aided design</u>, as well as general-purpose devices like <u>personal</u> <u>computers</u> and <u>mobile devices</u> like <u>smartphones</u>. Computers power the <u>Internet</u>, which links billions of other computers and users.

Early computers were meant to be used only for calculations. Simple manual instruments like the <u>abacus</u> have aided people in doing calculations since ancient times. Early in the <u>Industrial Revolution</u>, some mechanical devices were built to automate long tedious tasks, such as guiding patterns for <u>Iooms</u>. More sophisticated electrical <u>machines</u> did specialized <u>analog</u> calculations in the early 20th century. The first <u>digital</u> electronic calculating machines were developed during <u>World War II</u>. The first <u>semiconductor transistors</u> in the late 1940s were followed by the <u>silicon</u>-based <u>MOSFET</u> (MOS transistor) and <u>monolithic integrated circuit</u> (IC) chip technologies in the late 1950s, leading to the <u>microprocessor</u> and the <u>microcomputer revolution</u> in the 1970s. The speed, power and versatility of computers have been increasing dramatically ever since then, with <u>transistor counts</u> increasing at a rapid pace (as predicted by <u>Moore's law</u>), leading to the <u>Digital Revolution</u> during the late 20th to early 21st centuries.
